

packet sniffing

- Packet sniffing is a hacking technique that involves capturing data packets traveling through a network.
- This can be used to steal sensitive information or launch other attacks.

How it works

- Packet sniffers monitor network traffic
- They capture packets as they travel through a network
- They look inside the packets to discover any valuable information

A packet sniffing attack (or simply a sniffing attack) is a network-created threat where a malicious entity captures network packets intending to steal data traffic that may have been left unencrypted.

Packet sniffing tools:

Wireshark: Traces malicious traffic back to the source

Colasoft Capsa: Provides in-depth network analysis

NetworkMiner: A passive network sniffing tool that captures every packet

Kismet: An open-source software tool for wireless network monitoring

OmniPeek: A packet sniffer and network analyzer tool
